Abstract: Though the history of macrofungal studies on Turkish macromycota goes back to almost 100 years and the number of them have increased particularly in the last 3 decades, the accumulated data presents about 2400 taxa. Compared to the 15.000 assumed macrofungi of Europe and the macrofungal diversity estimates of Mueller et al. regarding the plant/macrofungus ratios of temperate regions, there is still much to be done to obtain the overall macrofungal data of Turkey. To contribute to the macrofungal biodiversity of Turkey, this study was carried out, and a new coprinoid species, *Leucocoprinus cepistipes* (Sowerby) Pat. belonging to the family Agaricaceae, is given as new record for the macromycota of Turkey from Ardeşen district of Rize province. The taxon is described briefly and photographs related to its macro and micromorphologies are given.

***Leucocoprinus cepistipes*, Türkiye Makromikotası için Yeni Bir Coprinoid Tür Kaydı**

Özet: Türkiye makromikotası ile ilgili çalışmaların tarihi neredeyse 100 yıl kadar geriye gitse ve bunların sayısı özellikle son 30 yılda artsa da, biriken data yaklaşık 2400 taksonu ortaya koymaktadır. Avrupada varlığı kabul edilen 15.000 mantar ve Mueller ve arkadaşlarının ilman bölgelerin bitki/makromantar çeşitliliğine ilişkin tahminleri ile karşılaştırıldığında, Türkiye'nin bütüncül makromantar datasının elde edilebilmesi için daha yapılması gereken çok işin olduğu muhakkaktır. Türkiye makromantar biyoçeşitliliğine katkı sağlamak amacıyla bu çalışma gerçekleştirilmiş ve Agaricaceae familyasına ait yeni bir coprinoid türü olan *Leucocoprinus cepistipes* (Sowerby) Pat., Rize'nin Ardeşen ilçesinden Türkiye makromikotası için yeni kayıt olarak verilmiştir. Takson kısaca betimlenerek makro ve mikromorfolojisine ait fotoğrafları verilmiştir.

1. Introduction

Leucocoprinus Pat. is a genus of the family Agaricaceae with about 40 species [1]. The members of the genus have a cosmopolitan distribution and characterized by small to medium, lepiotoid to coprinoid basidiocarp; convex to plane, membranous, radially sulcate or striate pileus; free, whitish and crowded lamellae; cylindrical, hollow, rarely bulbous, central stipe; membranous annulus; clavate, tetrasporic, sometimes bisporic to monosporic basidia; ellipsoid, hyaline, smooth, dextrinoid, thick walled and apically germ pored basidiospores. Though the members of the genus resemble the species of *Leucoagaricus* Locq. ex Singer and *Macrolepiota* Singer, they are differentiated from *Macrolepiota* by their small sized basidiocarps and by the absence of clamp connection, while they can be distinguished from *Leucoagaricus* by their fragile, coprinoid, plicate-sulcate pileal margins [2].

During our routine field studies, carried out to determine the macrofungal diversity of Ardeşen (Rize) district, within the scope of a university research fund project, some white coprinoid fungi samples were collected and identified as *Leucocoprinus cepistipes* (Sowerby) Pat.

So far six species of *Leucocoprinus* (*L. badhamii* (Berk. & Broome) Locq., *L. birnbaumii* (Corda) Singer, *L. cygneus* (J.E. Lange) Bon, *L. lanzonii* Bon, Migl. & Brunori, *L. straminellus* (Bagl.) Narducci & Caroti and *L. jubilaei* (Joss.) Wasser) [3, 4, 5, 6, 7, 8] have been recorded from Turkey, and the current checklists on the macromycota of Turkey [7, 8] and some latest contributory studies [9-25] indicate that *L. cepistipes* had not been recorded from Turkey yet.

The study aims to make a contribution to the mycobiota of Turkey.

2. Material and Method

Leucocoprinus Pat. samples were collected from Ardeşen (Rize) district in 2017. During collection necessary ecological and morphological characteristics of the samples were recorded and they were photographed in their natural habitat. Then the specimens were transferred to the lab within paper bags. Microscopic studies were carried out under Nikon Eclipse Ci trinocular light microscope. Photographs related to micromorphology were taken by DS-Fi2 digital camera. Meltzer's reagent was used to dye the histological preparations. The samples were identified with the help of Candusso and Lanzoni [26], Breitenbach and Kränzlin [27], Jordan [28], Lopez and Garcia [29], Pushpa and Purushothama [2], Kuo [30] and Desjardin et al. [31]. *Leucocoprinus* samples are kept at Karamanoğlu Mehmetbey University, Kamil Özdağ Science Faculty, Department of Biology.

3. Results

Sytematic of the taxon is in accordance with Kirk et al. (2008) and speciesfungorum.org (accessed on 20 July 2017). Description of macroscopic and microscopic characters, ecology, and the distribution of the species are provided, and discussed briefly.

Macroscopic features: Cap 30-50 mm in diameter, at first narrowly ovoid, then conic campanulate and finally broadly convex to plano-convex or seldomly plane, central obtuse umbo becomes apparent at maturity, surface pure white to greyish white, darker at the center, powdery with soft, whitish scales and granules, margin somewhat incurved, striate and splitting, often hung with scattered veil fragments. Flesh thin, soft, white, odour and taste mild to not distinctive. Gills free, white when young then pallid to pale puff. Stipe 40-70 × 4-7 mm, cylindrical, straight to sinuous, hollow, tapering towards the apex with a white membranous annulus on the upper part, somewhat bulbous at the base, sometimes with scattered soft powdery remains, white, surface smooth to sparsely pruinose (Figure 1).

Microscopic features: Basidia 25-30 × 9-13 µm, clavate, bearing four sterigmata. Cheilocystidia 35-60 × 12-18 µm, clavate to mucronate, with a long, flexuous neck, thin walled, smooth. Pleurocystidia not observed. Spores 8.5-11 × 5.5-6.8 µm, ellipsoid, hyaline, smooth (Figure 2), weakly to strongly dextrinoid; spore print white.

Figure 1. Basidiocarps of *Leucocoprinus cepistipes*

Ecology: Scattered to clustered on leaf litter or woody debris [2, 26, 31], cultivated soil, gardens [30], in flowerpots, greenhouses [1, 27, 28, 32] throughout the year.

Specimen examined: Rize-Ardeşen, Akdere village, roadside, on wood shavings, 41°08'N-41°02'E, 300 m, 13.10.2016, Yuzun 5334.

4. Discussion and Conclusion

Leucocoprinus cepistipes is a whitish and softly scaly-powdery capped lepiotoid mushroom that fruits primarily in parks, gardens, golf courses etc., as well as native woodlands especially on well decomposed woody litter. Generally the characteristics of the investigated sample coincide with those given in literature [2, 26-28, 31].

Leucocoprinus cepistipes had some similarities with some other agaricoid, lepiotoid and coprinoid taxa. For example, it may be confused with *Leucocoprinus brebissonii* (Godey) Locq., *L. birnbaumii* (Corda) Singer, *L. cretatus* Locq. and *L. lilacinogranulosus* (Hennings) Locq. in terms of general morphology or habitat. Among them, *L. brebissonii* grows freely in nature, usually in hardwood forests on leaf litter and have dark brown disc and squamules [26, 27]. *L. cretatus* differs with a snow-white and strongly floccose pileus and stipe [30] while *L. lilacinogranulosus* differs with pink to lilac squamules and a concolorous disc [27]. Likewise, *L. birnbaumii* is easily differentiated by a bright-yellow, finely-scaled, bell-shaped, striate cap, thin, collar-like annulus, and free, yellowish gills [4].

With this study, *Leucocoprinus cepistipes* was added to Turkish mycobiota as new record increasing the current taxa number of this genus to seven.

Acknowledgment

The authors would like to thank Karamanoğlu Mehmetbey University Research Fund for supporting the Project (16-M-16) financially.
